Flood Events and Flood Risk Milestones in the Netherlands

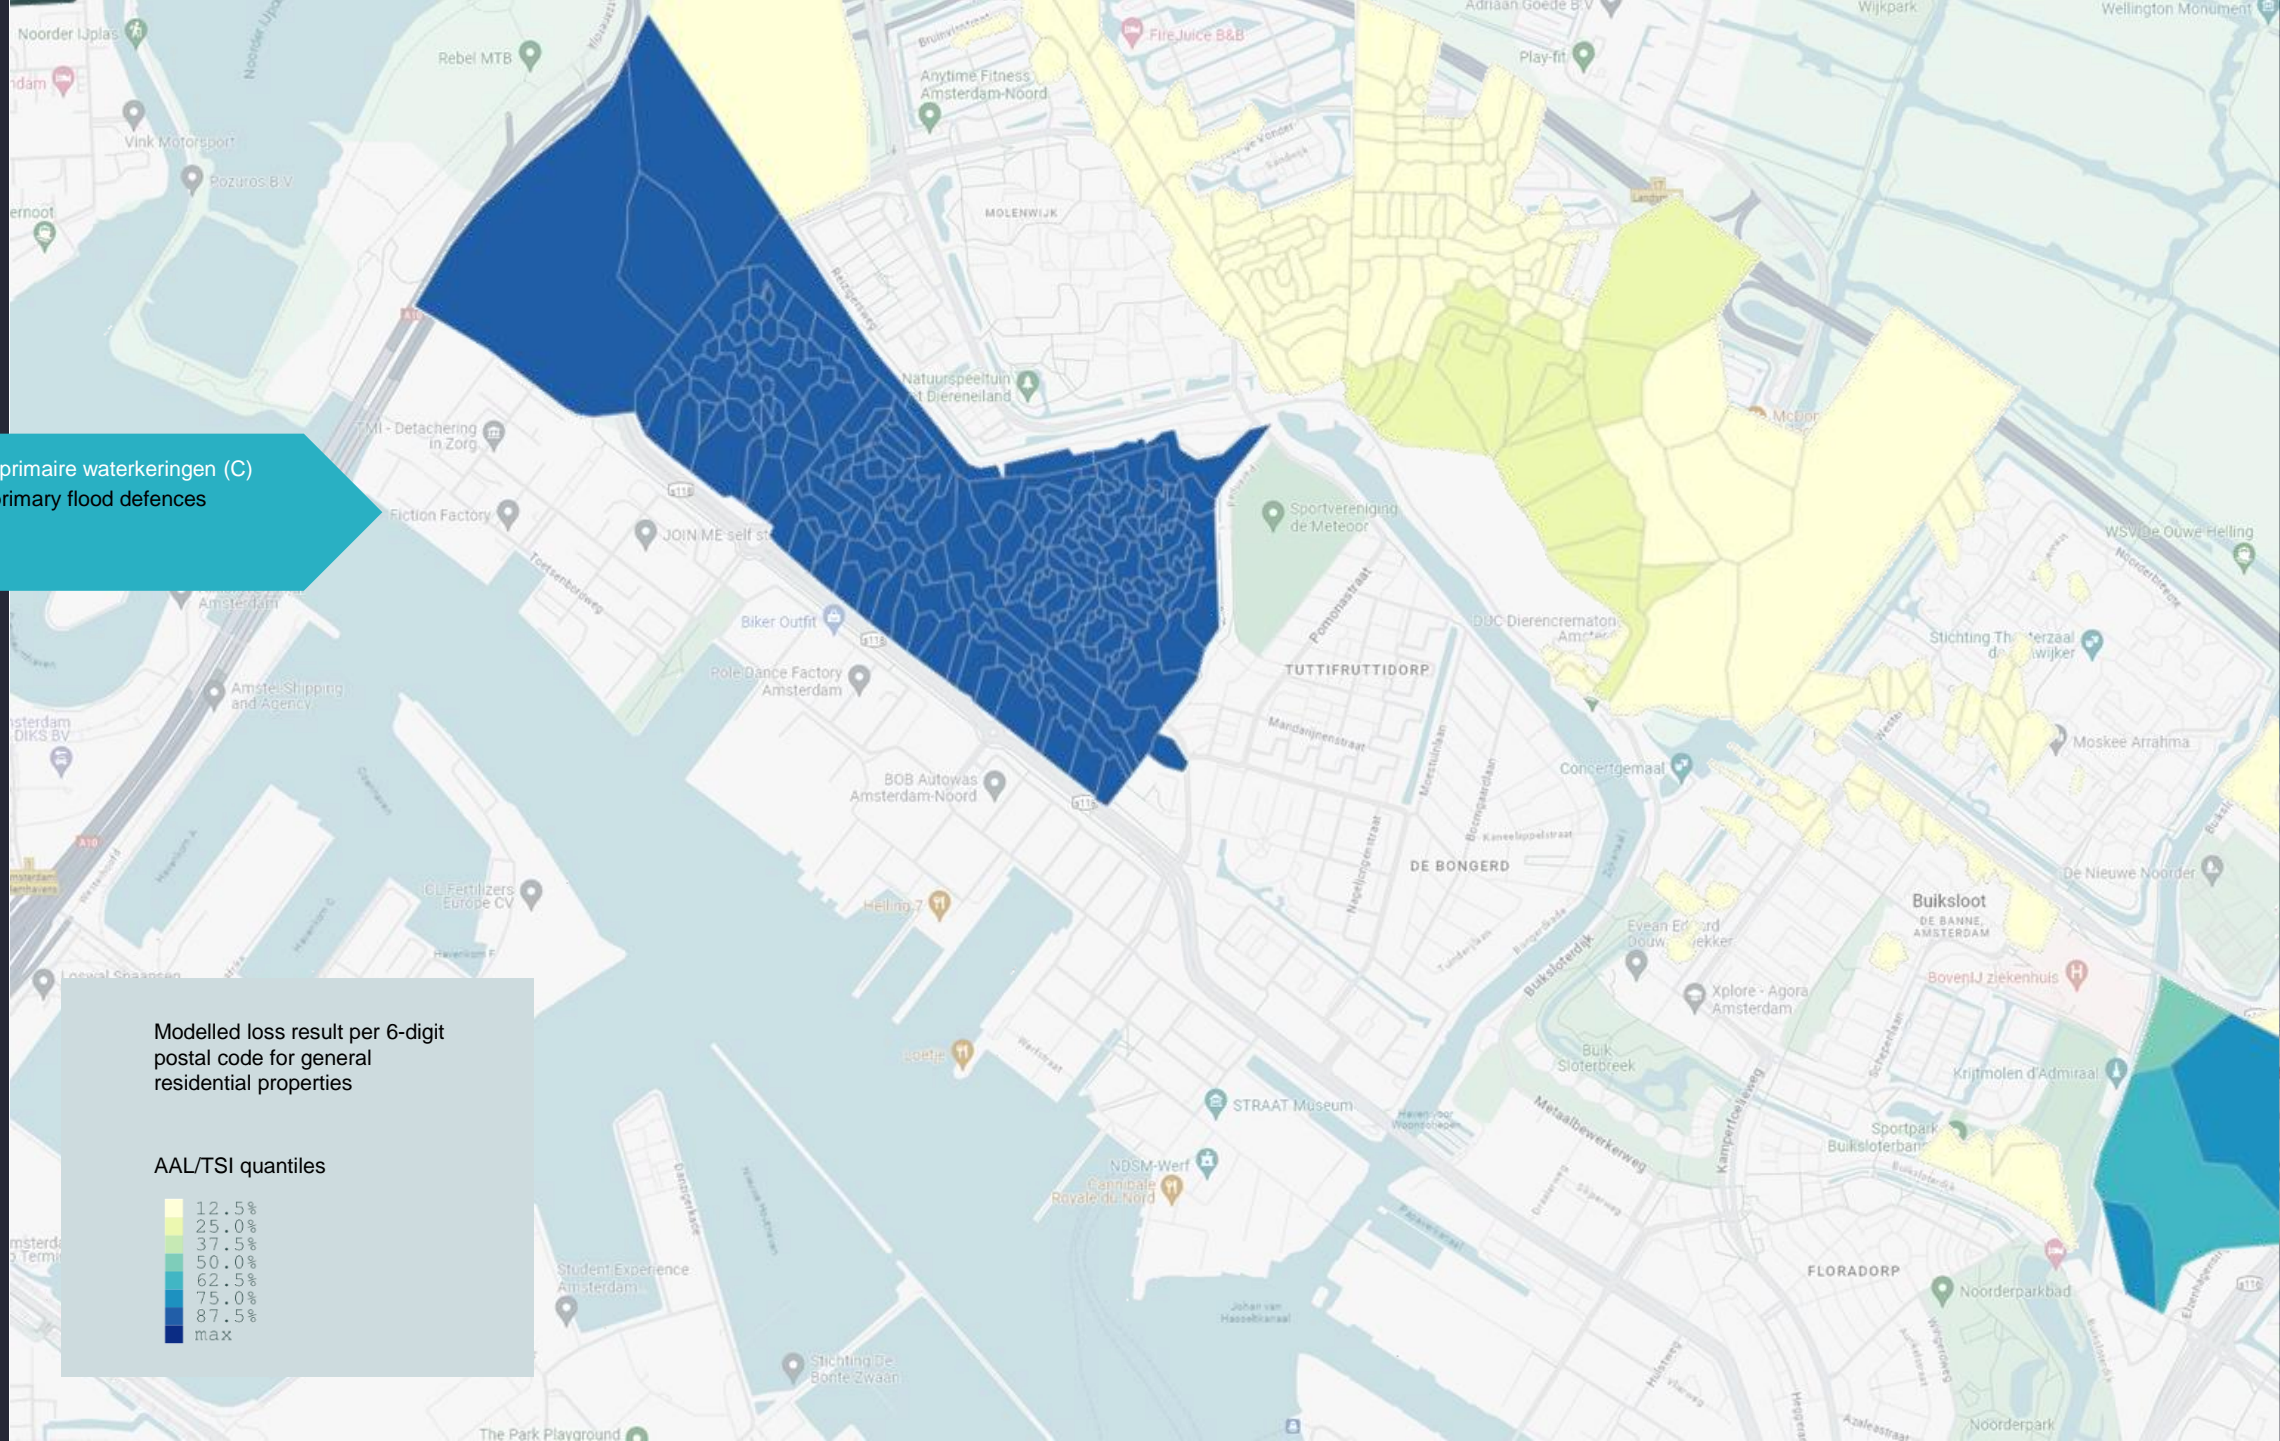

Doorbraak niet-primaire waterkeringen (C)
Failure of non-primary flood defences

Modelled loss result per 6-digit postal code for general residential properties

AAL/TSI quantiles

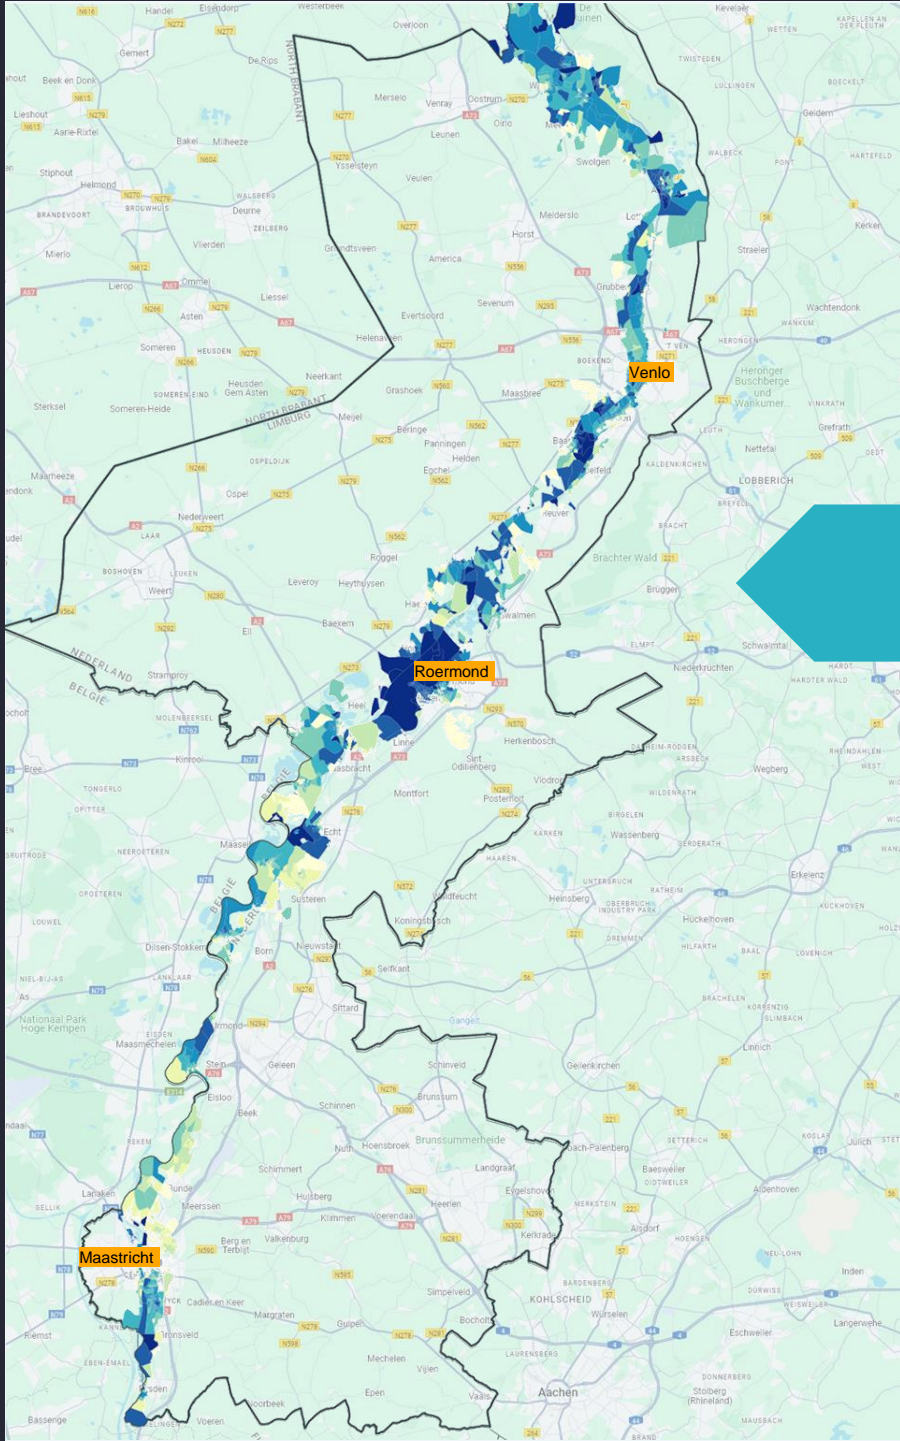

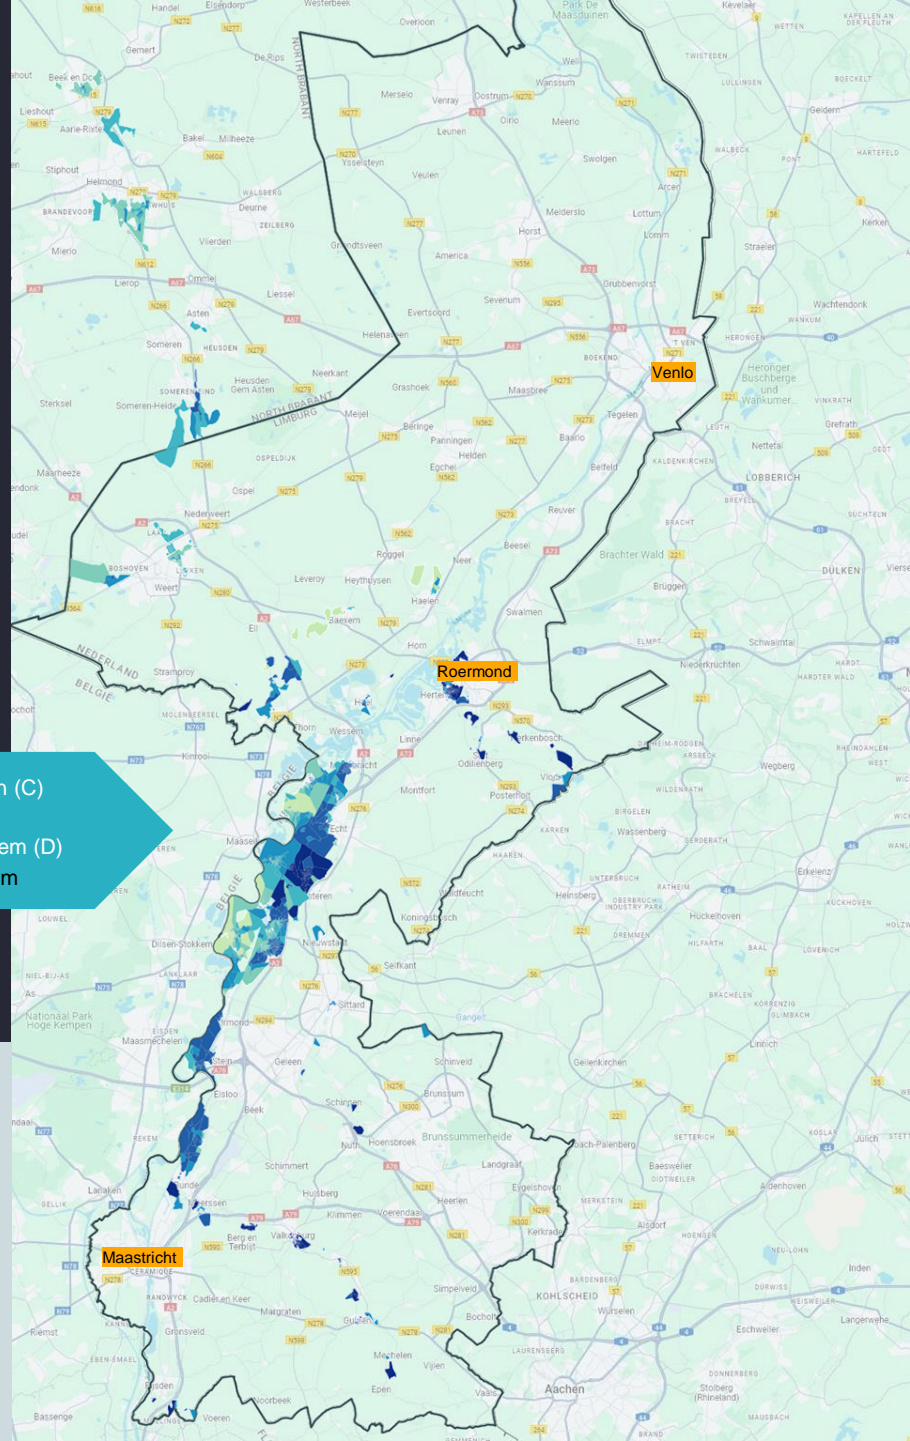

AON

Inundatie buitendijkse gebieden (A)
Floodng of unprotected areas

Doorbraak niet-primaire waterkeringen (C)
Failure of non-primary flood defences
Inundatie vanuit regionaal watersysteem (D)
Flooding from the regional watersystem

Modelled loss result per 6-digit
postal code for general
residential properties

AAL/TSI quantiles

Flood in The Netherlands

Primary

- A Inundatie buitendijkse gebieden**
Flooding of unprotected areas
- B Doorbraak primaire waterkeringen**
Failure of primary flood defences

Non-Primary and Pluvial

- C Doorbraak niet-primaire waterkeringen**
Failure of non-primary flood defences
- D Inundatie vanuit regionaal watersysteem**
Flooding from the regional watersystem
- P Wateroverlast bij hevige regenval**
Pluvial flood and cloud burst

AON

Exposure Geocoding

Precise coordinates

The Aon/ Impact Forecasting flood model for The Netherlands supports of the following input geocoding precisions:

- Exact coordinates on 25 x 25m grid: WGS84 (Lat/Lon). Previous model: 100 x 100m.
Street + house number

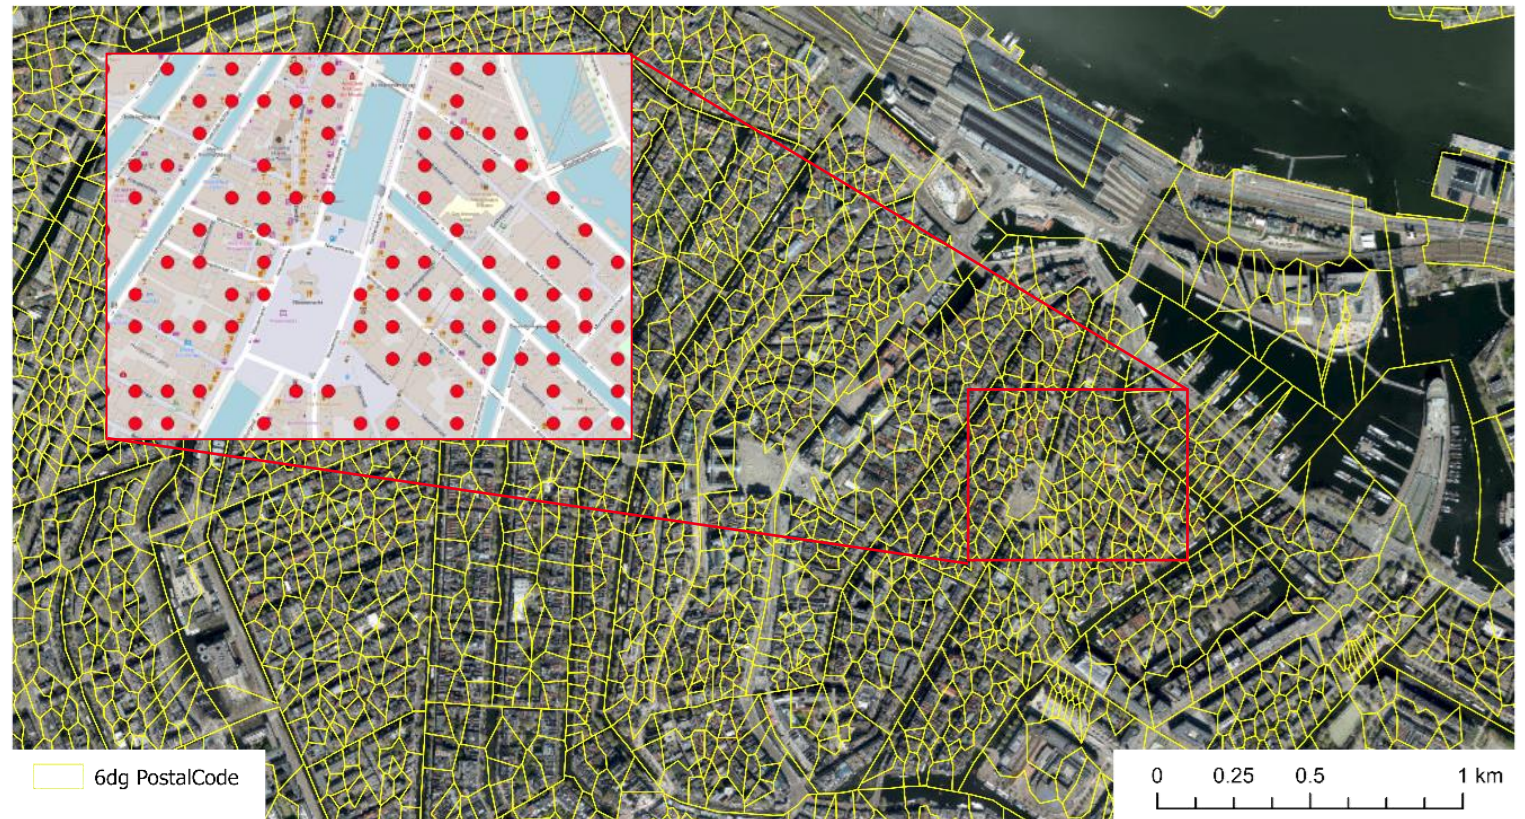

Geocoding illustrated: city of Amsterdam - center
25 x 25m grid (new released model, March 2023)

Exposure Geocoding

6-digit postal code

The Aon/ Impact Forecasting flood model for The Netherlands supports of the following input geocoding precisions:

- Exact coordinates on 25 x 25m grid: WGS84 (Lat/Lon). Previous model: 100 x 100m. Street + house number
- 6-digit postal code, re-shaped by IF (mapped to most prominent grid cell)

Geocoding illustrated: city of Amsterdam - center
6-digit postal codes

Exposure Geocoding

4-digit postal code

The Aon/ Impact Forecasting flood model for The Netherlands supports of the following input geocoding precisions:

- Exact coordinates on 25 x 25m grid: WGS84 (Lat/Lon). Previous model: 100 x 100m. Street + house number
- 6-digit postal code, re-shaped by IF (mapped to most prominent grid cell)
- 4-digit postal code (uses location sampling)

Various exposure location distributions (for 4-digit postal code) for residential, non-residential and agriculture property using CORINE Land Cover (CLC) and BAG building outlines and building purpose data

CLC: the 'Coordination of information on the environment' (Corine) is an inventory of European land cover and is available through the European Copernicus initiative.

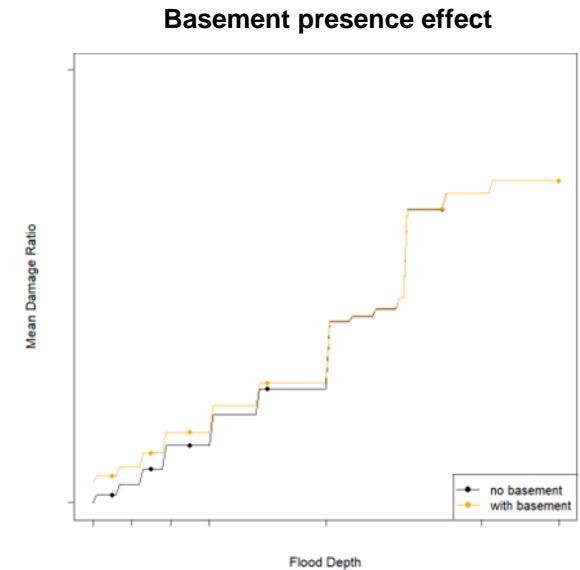

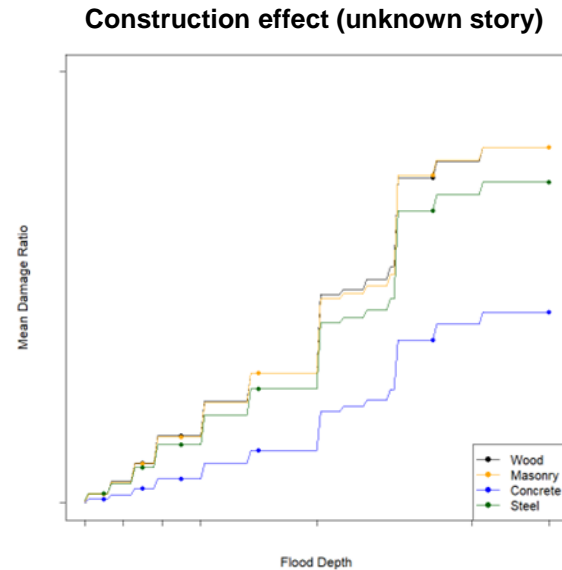

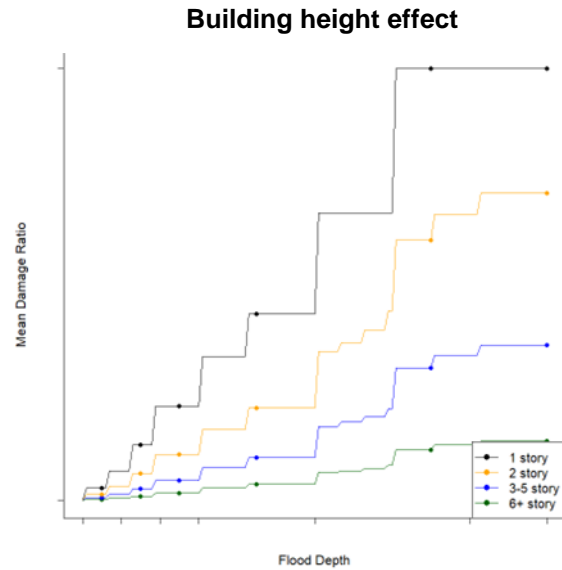

BAG: Basisregistratie adressen en gebouwen, dienst voor het kadaster en de openbare registers

Geocoding illustrated: city of Amsterdam – center
4-digit postal code

Vulnerability

Effect of primary modifiers

- Individual primary modifiers have effect on damageability
- Their effect is not independent (construction can affect building height and vice versa)

Vulnerability

Insights from Bernd losses

- Experience based re-assessment of vulnerability loss curves
- Cooperation between Leuven University and Aon Belgium
- Information gathered from media (newspapers, tv, internet) and Streetview to estimate inundation depths
- Flood depth in 39 municipalities was studied
- Bernd case-by-case loss database from Aon for different occupancy types: Residential, Commercial, Municipality, Agricultural
- Insights have been ported to Aon IF Flood model for The Netherlands

Manual estimates of the water depth

Geocoding and Unspecified Modifiers

IF classifies The Netherlands into 2 regions urban / rural when modelling general residential, industrial, commercial or agriculture line of business.

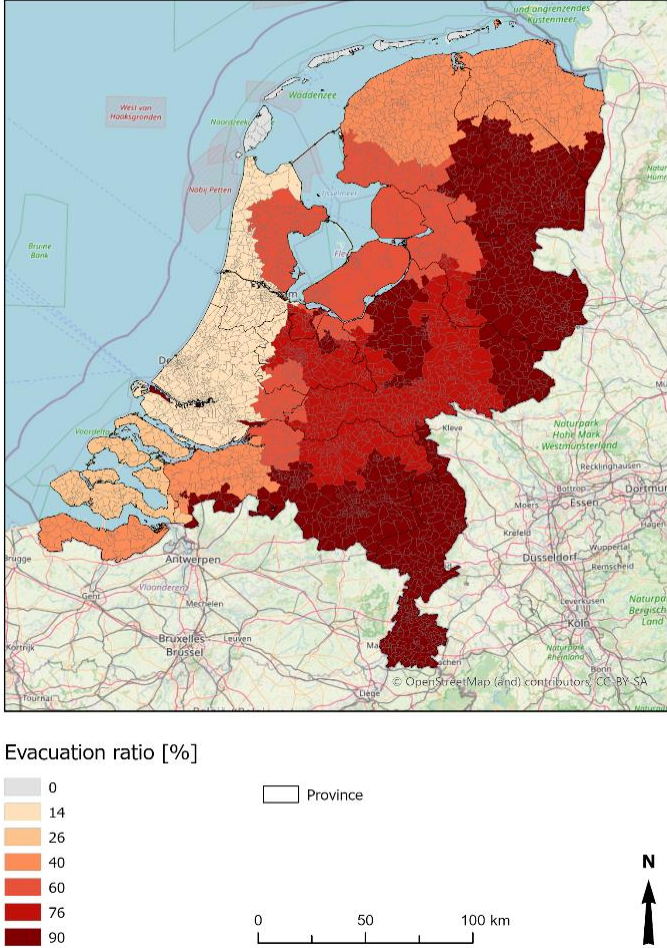

For Motor line of business IF now considers 7 tiers to model the evacuation rate when an event occurs (as per HKV, developed from LIWO)

These two modifiers are automatically assigned to the exposure (on corresponding PC4 level), and are reflected in the vulnerability

IFv2 Vulnerability regions

IFv2 Motor Hull evacuation rates

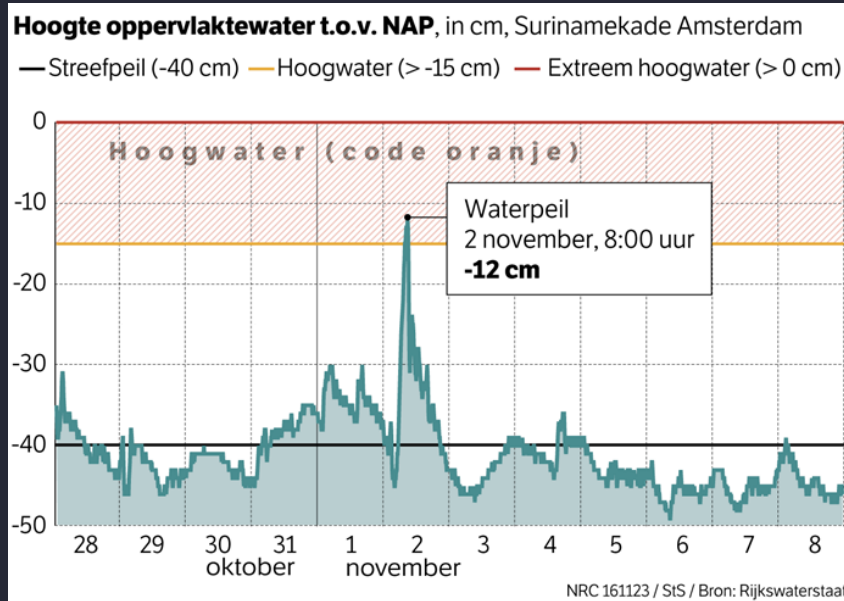

AON

Amsterdam

2 November 2023

Combination of

- Large volume of rainfall in preceding days
- Failure of IJmuiden sluiceway: after low-tide the valves refuse to close. When the tide turns, water from the North sea flows land-inwards.
- Effect elevated by upcoming storm Ciaran

Resulting in

- Wave of water rolls from IJmuiden to Wijk bij Duurstede
- Risk of streets Amsterdam flooding, sewage system overflowing, salinization of the regions fresh water (drinking water) system
- Closing of the 'IJ-front'
- At 7.26 sluice at IJmuiden repaired and closed

Modelled loss result per 6-digit postal code for general residential properties

AAL/TSI quantiles

Doorbraak primaire waterkeringen (B)
Failure of primary flood defences
